Evidence Companion

When Capability Creates Opportunity

Vincent Boucher President of MONTREAL.AI

27 October 2026

Evidence classification

Observed	Executed synthetic oracle calls, automatic sparse fits, artifact updates, fresh model/plan outcomes, transfer of actual bytes, native interface checks and resource-accounting identities.
Sourced	Official current model references and prices; external scientific-software and experiment-design provider list rates; pinned prior studies and foundation materials.
Assumed	Customer scopes and hours, arrivals, trust, willingness to pay, simulator tariffs and latency, token counts, operational overhead, collection delays, reserves and maintenance.
Simulated	Enterprise jobs, invoices, collections, profit, capacity allocation, counterparties and authority fixtures.
Unknown	Real willingness to pay, realized complete research/engineering cost, API entitlement and throughput, physical validity, live execution/authentication and sustained compounding.

Core study inventory

Item	Scope
Primary technical confirmation	48 tasks; 1,728 method/budget rows
Compound-offering confirmation	48 different tasks; 1,728 rows
Learning	1 origin + 10 Gym jobs; v1 9 terms, v2 21
Economic confirmation	11,520 histories: 30 scenarios x 6 policies x 64 seeds
Integration	29 unchanged upstream files; 29 directed controls
Customer revenue	USD 0 observed

Claim-to-evidence map

Claim	Companion evidence
Learning and source freeze	`technical/results/FREEZE.json`; `learning_ledger.json`; `technical/artifacts/`
Fresh primary outcomes	`technical/results/confirmation_rows.json`, CSV and paired analysis
New robust offering	`technical/robust/PROTOCOL.json`; PREDECLARED, FREEZE and fresh results
Conditional economics	`economics/scenario.json`; `policy_freeze.json`; `results/enterprise_runs.csv` and summary
Auditable event histories	Six complete representative seed-0 ledgers, matched events and deterministic replay for every retained per-seed outcome

Admission / controlled transfer	`integration/results/development-admission-v1/`; conformance and recipient replay receipts
Source history	`source_audit.md`; `integration/source_manifest.json`; `sources/source_dossier.md`
Independent internal review	`validation/independent_review.md` and JSON; resource reservation probes

What was corrected and preserved

The original economic implementation accessed the realized stopping cost of a fresh direct search before deciding whether the job fit remaining cash and capacity. Boundary probes reproduced the error. Corrected code reserves the declared maximum first, accesses protected outcomes only after commitment and releases unused resources afterward. Original source and original policy freeze remain in the history; development-selected prices, routes and decisions were not retuned on confirmation. The final results explicitly report that execution uses an amended source.

The original protocol's portfolio prose mentioned lowest-cost/global-regret quality even though the operational acceptance required a feasible checked plan. A separate deliverable sentence over-specified a response model for direct-search delivery. Companion clarifications retain the original text and specify the actual implemented contract. The paper never attributes optimality or an accurate model to the direct baseline.

Research costs and validation

The primary model service charges 384 extra acceptance labels per customer delivery. The simple-plan service includes its final observation inside the displayed budget. The compound mission includes sixteen final observations inside its whole budget. Protected model and full-menu audits are research work, counted separately and shared across comparator scoring where applicable. The primary confirmation uses 44,544 unique oracle-equivalent audit observations, worth USD 4,454.40 only under the assumed USD 0.10 tariff. The separate compound-offering campaign uses 617,544 query-equivalent evaluations, including development, confirmation, full-menu audits and the illustrative replay. At the same hypothetical tariff, its common research expense alone is USD 61,754.40. Its operating sensitivity rows exclude this disclosed research burden; they are not whole-study profit. Actual observed paid API cash expense is zero. CPU time and unmeasured engineering monetary costs remain distinct. Whole-study payback is not established.

Recorded research phase	Query-equivalent units
Original construction learning run	11,396
Final origin plus ten Gym jobs	11,616
First-task development smoke	2,728
Full 12-task development	33,921
Full 48-task confirmation	134,716
Robust 12-task development	123,690
Robust 48-task confirmation	493,814
Illustrative robust crossing replay	40
Recipient replay mission-fixture preparation	39
Separate protected integration recipient	968
Documented resource subtotal	812,928

This is a documented workload subtotal, not a certified complete research cost. It includes deliberate repeated construction and smoke campaigns. The original constructor's audit count is reconstructed from the executed routine rather than a separately preserved audit file. Common audit labels are counted once per task and campaign; literal recomputation of 8,576 already-known robust replay labels would raise the subtotal to 821,504. At the hypothetical USD 0.10 tariff, the two subtotals are USD 81,292.80 and USD 82,150.40. No corresponding invoice was incurred. Engineering effort, plotting, bootstrap, review and ordinary computing costs are unmetered. Paid-origin observations and the Gym already present in a policy's A/C ledger must not be charged again when allocating these study

costs. This resource inventory does not justify subtracting the whole campaign mechanically from every simulated enterprise.

Statistical interpretation

The main and robust experiments each contain 24 compatible, 12 partially shifted and 12 novel-family tasks. Bootstrap or binomial uncertainty describes this generator, not market truth. A post-hoc best-of-conventional envelope is a generous diagnostic and cannot be dispatched without additional information. The real policies use development outcomes only. No isolated positive case establishes high-reliability operation; infeasible menus and failed transfers remain in their original denominators.

Access and authority

The conformance lane uses artificial positive monetary evidence to exercise rights and revocation branches. The actual candidate's development-evidence gate rejects it, and corresponding retrieval attempts remain denied. A separately authorized research replay transports actual bytes and checks a fresh task. Fixture identities are not live ENS resolution. Revocation blocks new mediated access; it cannot erase copies already received. Production scientific scope remains unsupported, and Jobs/governance/settlement authority is unchanged.

Reproduction and publication

Start with the companion README and preserve the original evidence before rerunning. The numerical pipeline requires Python with NumPy, SciPy and scikit-learn; charts use Matplotlib; integration uses Node and the pinned vendored interfaces. LaTeX rebuild commands and environment versions accompany the source. Browser evidence is self-contained and bilingual. Full repository CI, flagship Pages deployment and production commissioning remain separate from this experimental research edition.

Author and assistance. Vincent Boucher, President of MONTREAL.AI. AI assistants performed research, code construction, execution, internal review, analysis and drafting. Internal review is not external scientific replication.
New source is Apache-2.0; original vendored licenses are preserved.
