Executive brief

AGI ALPHA FLYWHEEL — When Capability Creates Opportunity

Transformational Intelligence, Experience-Trained Specialists and the Expanding Frontier of Profitable Work

Vincent Boucher — President of MONTREAL.AI

27 October 2026 · Executed research and conditional economics

Strongest supported achievement

The team constructed an exact instrument that can answer a specified question while retaining unresolved measurement readings. It passed **50 of 50 comparisons covering 877,728 possible histories**. On **36 fresh authored cases**, it resolved **12 original questions**; treating each row's calibration independently resolved only six. Every endpoint had a valid extremal history, and all 12 unsupported-input probes were refused.

The instrument is useful within its declared model. **It does not earn the requested flagship claim.** The idea was absent from the supplied application brief, but certain-answer databases, uncertainty-aware query systems and query-guided cleaning already cover its core. A competent exact conventional method ties. No substantive advance beyond that prior art was demonstrated.

What the search contributed

Two independent automated search arms each used six web queries, with the same maximum candidate allowance. A general prompt produced three candidates; an expert restriction-first process produced four. The candidate set spanned mine-waste qualification, crop evidence, instrument restoration, archival claims, causal bounds, physical observables and chemical fingerprints. Raw records and rejection reasons are preserved.

The archival candidate was selected for a bounded falsification experiment, with flagship status withheld. The remaining opportunity hypothesis is to construct faithful source uncertainty models more cheaply, so useful scientific questions can be answered before complete transcription is affordable. This source-to-model advantage was not measured. One search per arm, unknown token expenditure and no human-expert trial cannot establish beyond-human foresight or a numerical Operational Alpha gain.

The connected example

Eight authored readings each retain two interpretations. The original question asks whether the late-period mean exceeds the early-period mean by more than 0.35 units. With a shared uncertain calibration and one allowed ±0.1 row error, the exact contrast interval is **[0.375, 1.625]**: every admitted history supports the claim.

Allow independent calibration by period and the interval becomes **[−0.425, 2.425]**. The same question is unresolved, with actual counterexamples. Source evidence must justify the shared calibration. These are authored cases, not a climate finding or a validated historical archive.

The source-access review found that the literature-linked ten-page dataset reports restricted access. Its public metadata and the correction are retained; no protected payload was retrieved. A real-image benchmark remains unrun.

Commercial result: baseline launch rejected

The proposed customer buys a source-grounded, decisive answer to the unchanged original question. Unresolved, unsupported or unaccepted work earns no success fee and returns the deposit. The complete forward model includes source interpretation, independent validation, failed attempts, bounded correction, acquisition, support, overhead, payment charges, default, refunds and financing.

The best tested success fee is **USD 800**, selected from seven prices before fresh confirmation. Every baseline exploratory price loses money. Each final scenario averages 600 hypothetical 90-day campaigns:

Scenario	Contracts	Useful accepted by day 90	Earned modeled revenue	Operating profit	Modeled loss frequency
Low	1.29	0.23	USD 176	−USD 2,377	100%
Baseline	23.59	9.165	USD 7,116	**−USD 810**	**69.0%**
High	48.69	21.86	USD 17,147	**+USD 6,283**	0.5%

The baseline mean-profit Monte Carlo interval is **−USD 951 to −USD 668**. It measures simulation noise under assumed inputs, not confidence in a real business. The declared robustness grid has **zero profitable cells out of 12** across its adverse corners. The favorable case remains a conditional positive scenario before sunk development.

The model charges USD 5 acquisition cash per originating opportunity, separately from intake labor. Even zero cash acquisition leaves the final baseline near break-even at −USD 59; USD 15 per origin lowers it to −USD 2,312. A competent human outside option needing only ten additional analysis minutes removes almost all demand. The model does not hold demand constant as prices rise.

An earlier +USD 467 baseline omitted costs and was superseded after independent review. Scheduling, zero-event reporting, acquisition, queue finance, pending fees and a human-comparator error all have preserved correction records. The corrected version was frozen before a new confirmation seed.

Cash, costs and investment

Baseline gross modeled receipts are USD 11,664.80, while earned modeled revenue is USD 7,115.56. Deposits, refunds and open work explain much of the difference. Contribution is USD 763.78; after USD 1,572.95 fixed campaign cost and USD 0.52 finance, operating profit is −USD 809.68.

Modeled day-90 cash of USD 5,746.50 includes initial owner funding. After listed deposits, refund reserves, payables, completion obligations, fee buffers and debt, free funds are USD 2,266.06. These include remaining owner capital and are not profit or an actual growth budget. Operating comparisons are before income tax, optional retention and sunk research.

Actual revenue and collections are USD 0. Complete actual research expenditure is unknown. Human-led demonstrator effort is separately estimated at 30/80/180 hours, or roughly USD 3.4k/9.2k/20.6k internal cost. A source-verified deployment has a different 250/700/1,600-hour scope. These are planning assumptions using sourced wage anchors, not human trials, market prices or evidence of agent superiority.

What the network inherits

The package provides the exact engine, independently authored exhaustive reference, proof, frozen generators, every case and result, refusal tests, source correction, business model and failed versions. Twelve fresh recipient processes reproduce the retained artifact's outputs, but an identical-content ordinary library is byte-identical. **All 12 successor queries remain unresolved.** Transfer is technically successful; useful successor acceptance and incremental retained Alpha are not established.

Primary E/U/library economics are explicitly equal. Extra retention is rejected at zero measured benefit. Native Insight, Nova-Seed, FusionPlan and accounting components execute from a verified 44-file source closure. Tampered artifacts are refused, the unsupported scientific production scope is refused, and unknown costs prevent a complete-cost seal. No live ENS authority, blockchain transaction, mint, listing or fund movement occurs.

Next decisive validation

The next proposal is a **rights-cleared source-to-answer pilot on 12 fresh questions**, with a separate development set and independent domain adjudication. Compare competent human-led uncertainty modeling, ordinary frontier-model use and expert operation with the checker under equal evidence and budgets. Preserve every source exclusion, correction and unresolved original query.

The optional unfunded plan caps estimated research at approximately **USD 5,100**, including 38 professional hours and source/tool allowances. Stop for unsupported accepted claims, absent source rights, no useful answers or no credible cost/value advantage. A partner's explicit outside option and conditional paid acceptance would test demand. This is the smallest useful route toward the remaining hypothesis; no new breakthrough or launch is promised.

Reproduction: `python study/reproduce.py --out /tmp/new-alpha-reproduction`. A clean isolated run matched 189 core files, 25 economic outputs and the regenerated frozen policy. The paper and full methods explain the evidence boundary and publication handoff.
