AGI ALPHA FLYWHEEL

When Capability Creates Opportunity

Executive brief

Vincent Boucher President of MONTREAL.AI

27 October 2026

The result worth acting on

A reusable representation learned from earlier simulator jobs improves fresh model construction. More consequentially, it helps deliver one operating plan that passes sixteen environmental checks inside a small total observation budget. The effect is strongest when the new work shares the learned structure.

Fresh compatible tasks	Developed v2	Strong conventional arm
Accurate model, 24-call candidate budget	21/24	1/24
Robust plan, 40 total calls	17/24	7/24

The candidate budget includes visible validation and any required plan check. The model service additionally pays for 384 independent verification observations. The robust-plan budget already includes all sixteen final context measurements. The latter is a useful, checked output rather than merely a better prediction score.

Where the advantage disappears

For one satisfactory operating point, direct search often avoids building a model. Across all families at 24 calls it succeeds in 27/48 cases, versus v2's 22/48. At 96 calls the strongest methods tie on 44/48 single-plan outcomes. The robust-plan gain also weakens under distribution shift and larger budgets. An ordinary library with exactly the same content matches v2. The diagnostic idea is defeated by a simpler paired-measurement baseline.

What the economics say

The primary, explicitly simulated 30-day enterprise earns mean operating profit of USD 46,781 using competent Beta delivery under assumed demand and prices. The optional policies reject retention and Gym spending; assessing the candidate still costs money and capacity. A predeclared 40-call fitting-cap scenario gives the controlled Gym pilot a conditional USD 4,439 increment, but that is not the unrestricted primary result and is not earned revenue. **Actual customer collections are USD 0.** Human scopes, arrivals, trust, simulator tariffs and token volumes are assumptions. Published external scientific-software rates anchor the price scenarios; they do not establish demand.

What to offer first

Offer a bounded scientific-software qualification engagement. Obtain a customer's real simulator and freeze the useful outcome, query cost, latency, acceptance and customer effort. Price against matched human delivery and buyer value. Compare the best conventional workflow, the retained representation and direct workarounds. Charge final checking and correction. Preserve the option to deliver profitably with no skill retention.

The next worthwhile experiment

Target a compound outcome whose verification requires many conditions and where repeated direct trial becomes expensive. Establish an observable way to identify compatible simulator families; the research's hidden family labels cannot route live work. Test the actual modern frontier tool-use configuration with the same context, code, tools and correction budget. Do not make model training compulsory.

A cautious investment policy can be successful

The real development-evidence admission assay rejects v2 in both tested envelopes after uncertainty and lifecycle costs. The protected research transfer passes 29 conformance checks with fixture identities and real bytes; it does not override that rejection. Production scientific execution remains outside the current capsule scope. Existing Jobs validation, governance and settlement are preserved.

What this edition does not establish

It does not establish live customer demand, live frontier-model superiority, live ENS authentication, graph-specific value, specialist ASI, autonomous business invention or sustained self-acceleration. Software learning and fresh synthetic outcomes were executed; the market was simulated. The robust offering was researcher proposed from the initial development finding and confirmed on separate fresh seeds. **Research is not free.** The compound-offering campaign used 617,544 query-equivalent evaluations. At the hypothetical USD 0.10 tariff, those alone would cost USD 61,754.40. Operating contributions exclude that separately disclosed common research burden; whole-study profitability is not established. Actual observed paid API cash expense was zero, while complete engineering cost remains unknown.

Inspect the mechanism

The full paper, LaTeX project, actual learned artifacts, raw results, frozen policies, accounting corrections, integration receipts, source audit and English/French demonstration are included in the research companion. The before/after resource-reservation defect is preserved; corrected economics reserve the whole declared obligation before accessing realized outcomes.
